[Comprehension Type Questions]

Comprehension #1

Geometrical isomerism is a kind of stereoisomerism which is present in the compounds containing a double bond (C = C, C = N, N = N) and arise due to the restricted or frozen rotation about the double bond. The atoms or groups attached to the doubly bonded carbons must be different. In aldoximes, the isomer is named as syn if hydrogen and hydroxyl groups are on the same side of C = N bond and if these are on opposite sides, the isomer is named as anti. In ketoximes, the prefixes syn and anti indicate which group of ketoxime is syn or anti to hydroxyl group.

The optical isomers rotate the plane of plane - polarised light. A sp³ hybridised carbon atom attached to four different atoms or groups is called an asymmetrical centre or chiral centre. The stereoisomers that are not mirror images of each other are called diastereomers. A mesoisomer has a plane of symmetry and is optically inactive due to internal compensation.
