

# QUADRILATERALS

## IMPORTANT POINTS

- ◆ A quadrilateral is a figure bounded by four line segments such that no three of them are parallel.
- ◆ Two sides of quadrilateral are consecutive or adjacent sides, if they have a common point (vertex).
- ◆ Two sides of a quadrilateral are opposite sides, if they have no common end-point (vertex).
- ◆ The consecutive angles of a quadrilateral are two angles which include a side in their intersection. In other words, two angles are consecutive, if they have a common arm.
- ◆ Two angles of a quadrilateral are said to be opposite angles if they do not have a common arm.
- ◆ The sum of the four angles of a quadrilateral is  $360^\circ$ .

## EXAMPLES

**Ex.1** In a quadrilateral ABCD, the angles A, B, C and D are in the ratio 2 : 4 : 5 : 7. Find the measure of each angles of the quadrilateral.

**Sol.** We have  $\angle A : \angle B : \angle C : \angle D = 2 : 4 : 5 : 7$ .  
So, let  $\angle A = 2x^\circ$ ,  $\angle B = 4x^\circ$ ,  $\angle C = 5x^\circ$ ,  $\angle D = 7x^\circ$ .

$$\therefore \angle A + \angle B + \angle C + \angle D = 360^\circ$$

$$\Rightarrow 2x + 4x + 5x + 7x = 360^\circ$$

$$\Rightarrow 18x = 360^\circ$$

$$\Rightarrow x = 20^\circ$$

Thus, the angles are :

$$\angle A = 40^\circ, \angle B = (4 \times 20)^\circ = 80^\circ,$$

$$\angle C = (5 \times 20)^\circ = 100^\circ$$

$$\text{and, } \angle D = (7x)^\circ = (7 \times 20)^\circ = 140^\circ$$

**Ex.2** The sides BA and DC of a quadrilateral ABCD are produced as shown in fig.

Prove that  $a + b = x + y$ .

**Sol.** Join BD. In  $\triangle ABD$ , we have

$$\angle ABD + \angle ADB = b^\circ \quad \dots(i)$$

In  $\triangle CBD$ , we have

$$\angle CBD + \angle CDB = a^\circ \quad \dots(ii)$$

Adding (i) and (ii), we get

$$(\angle ABD + \angle CBD) + (\angle ADB + \angle CDB) = a^\circ + b^\circ$$

$$\Rightarrow x^\circ + y^\circ = a^\circ + b^\circ$$

Hence,  $x + y = a + b$

**Ex.3** In a quadrilateral ABCD, AO and BO are the bisectors of  $\angle A$  and  $\angle B$  respectively. Prove that  $\angle AOB = \frac{1}{2}(\angle C + \angle D)$ .

**Sol.** In  $\triangle AOB$ , we have

$$\angle AOB + \angle 1 + \angle 2 = 180^\circ$$

$$\Rightarrow \angle AOB = 180^\circ - (\angle 1 + \angle 2)$$

$$\Rightarrow \angle AOB = 180^\circ - \left( \frac{1}{2} \angle A + \frac{1}{2} \angle B \right)$$

$$\left[ \because \angle 1 = \frac{1}{2} \angle A \text{ and } \angle 2 = \frac{1}{2} \angle B \right]$$

$$\begin{aligned}\Rightarrow \angle AOB &= 180^\circ - \frac{1}{2} (\angle A + \angle B) \\ \Rightarrow \angle AOB &= 180^\circ - \frac{1}{2} [360^\circ - (\angle C + \angle D)] \\ [\because \angle A + \angle B + \angle C + \angle D &= 360^\circ] \\ \therefore \angle A + \angle B &= 360^\circ - (\angle C + \angle D) \\ \Rightarrow \angle AOB &= 180^\circ - 180^\circ + \frac{1}{2} (\angle C + \angle D) \\ \Rightarrow \angle AOB &= \frac{1}{2} (\angle C + \angle D)\end{aligned}$$

**Ex.4** In figure bisectors of  $\angle B$  and  $\angle D$  of quadrilateral ABCD meet CD and AB produced at P and Q respectively. Prove that

$$\angle P + \angle Q = \frac{1}{2} (\angle ABC + \angle ADC)$$

**Sol.** In  $\triangle PBC$ , we have

$$\therefore \angle P + \angle 4 + \angle C = 180^\circ$$

$$\Rightarrow \angle P + \frac{1}{2} \angle B + \angle C = 180^\circ \quad \dots(i)$$

In  $\triangle QAD$ , we have  $\angle Q + \angle A + \angle 1 = 180^\circ$

$$\Rightarrow \angle Q + \angle A + \frac{1}{2} \angle D = 180^\circ \quad \dots(ii)$$

Adding (i) and (ii), we get

$$\begin{aligned}\angle P + \angle Q + \angle A + \angle C + \frac{1}{2} \angle B + \frac{1}{2} \angle D \\ = 180^\circ + 180^\circ\end{aligned}$$

$$\Rightarrow \angle P + \angle Q + \angle A + \angle C + \frac{1}{2} \angle B + \frac{1}{2} \angle D = 360^\circ$$

$$\Rightarrow \angle P + \angle Q + \angle A + \angle C + \frac{1}{2} (\angle B + \angle D)$$

$$= \angle A + \angle B + \angle C + \angle D$$

$$[\because \text{In a quadrilateral ABCD } \angle A + \angle B + \angle C + \angle D = 360^\circ]$$

$$\Rightarrow \angle P + \angle Q = \frac{1}{2} (\angle B + \angle D)$$

$$\Rightarrow \angle P + \angle Q = \frac{1}{2} (\angle ABC + \angle ADC)$$

**Ex.5** In a parallelogram ABCD, prove that sum of any two consecutive angles is  $180^\circ$ .

**Sol.** Since ABCD is a parallelogram. Therefore,  $AD \parallel BC$ .

Now,  $AD \parallel BC$  and transversal AB intersects them at A and B respectively.

$$\therefore \angle A + \angle B = 180^\circ$$

[ $\because$  Sum of the interior angles on the same side of the transversal is  $180^\circ$ ]

Similarly, we can prove that

$$\angle B + \angle C = 180^\circ, \angle C + \angle D = 180^\circ \text{ and } \angle D + \angle A = 180^\circ.$$

- ◆ A quadrilateral having exactly one pair of parallel sides, is called a trapezium.
- ◆ A trapezium is said to be an isosceles trapezium, if its non-parallel sides are equal.
- ◆ A quadrilateral is a parallelogram if its both pairs of opposite sides are parallel.
- ◆ A parallelogram having all sides equal is called a rhombus.
- ◆ A parallelogram whose each angle is a right angle, is called a rectangle.
- ◆ A square is a rectangle with a pair of adjacent sides equal.
- ◆ A quadrilateral is a kite if it has two pairs of equal adjacent sides and unequal opposite sides.
- ◆ A diagonal of a parallelogram divides it into two congruent triangles.
- ◆ In a parallelogram, opposite sides are equal.
- ◆ The opposite angles of a parallelogram are equal.
- ◆ The diagonals of a parallelogram bisect each other.
- ◆ In a parallelogram, the bisectors of any two consecutive angles intersect at right angle.
- ◆ If diagonal of a parallelogram bisects one of the angles of the parallelogram, it also bisects the second angle.
- ◆ The angle bisectors of a parallelogram form a rectangle.

**Ex.6** In a parallelogram ABCD,  $\angle D = 115^\circ$ , determine the measure of  $\angle A$  and  $\angle B$ .

**Sol.** Since the sum of any two consecutive angles of a parallelogram is  $180^\circ$ . Therefore,

$$\angle A + \angle D = 180^\circ \text{ and } \angle A + \angle B = 180^\circ$$

$$\text{Now, } \angle A + \angle D = 180^\circ$$

$$\Rightarrow \angle A + 115^\circ = 180^\circ [\because \angle D = 115^\circ \text{ (given)}]$$

$$\Rightarrow \angle A = 65^\circ \text{ and } \angle A + \angle B = 180^\circ$$

$$\Rightarrow 65^\circ + \angle B = 180^\circ \Rightarrow \angle B = 115^\circ$$

$$\text{Thus, } \angle A = 65^\circ \text{ and } \angle B = 115^\circ$$

**Ex.7** In figure,  $AB = AC$ ,  $\angle EAD = \angle CAD$  and  $CD \parallel AB$ . Show that ABCD is a parallelogram.

**Sol.** In  $\triangle ABC$ ,  $AB = AC$  [Given]

$$\Rightarrow \angle ABC = \angle ACB \quad \dots(1)$$

(Angles opposite the equal sides are equal)

$$\angle EAD = \angle CAD [\text{Given}] \dots(2)$$

Now,  $\angle EAC = \angle ABC + \angle ACB$   
 (An exterior angle is equal to sum of two interior opposite angles of a triangles)

$$\Rightarrow \angle EAD + \angle CAD = \angle ABC + \angle ACB$$

$$\Rightarrow \angle CAD + \angle CAD = \angle ACB + \angle ACB$$

By (1) and (2)

$$\Rightarrow 2\angle CAD = 2\angle ACB$$

$$\Rightarrow \angle CAD = \angle ACB$$

$$\Rightarrow BC \parallel AD$$

Also,  $CD \parallel AB$  [Given]

Thus, we have both pairs of opposite sides of quadrilateral ABCD parallel. Therefore, ABCD is a parallelogram.

**Ex.8** ABCD is a parallelogram and line segments AX, CY are angle bisector of  $\angle A$  and  $\angle C$  respectively then show  $AX \parallel CY$ .

**Sol.** Since opposite angles are equal in a parallelogram. Therefore, in parallelogram ABCD, we have  $\angle A = \angle C$

$$\Rightarrow \frac{1}{2} \angle A = \frac{1}{2} \angle C$$

$$\Rightarrow \angle 1 = \angle 2 \quad \dots(i)$$

$[\because AX$  and  $CY$  are bisectors of  $\angle A$  and  $\angle C$  respectively]

Now,  $AB \parallel DC$  and the transversal  $CY$  intersects them.

$$\therefore \angle 2 = \angle 3 \quad \dots(ii)$$

$[\because$  Alternate interior angles are equal]

From (i) and (ii), we get

$$\angle 1 = \angle 3$$

Thus, transversal  $AB$  intersects  $AX$  and  $YC$  at  $A$  and  $Y$  such that  $\angle 1 = \angle 3$  i.e. corresponding angles are equal.

$$\therefore AX \parallel CY$$

**Ex.9** In the adjoining figure, a point  $O$  is taken inside an equilateral quad. ABCD such that  $OB = OD$ . Show that  $A, O$  and  $C$  are in the same straight line.

**Sol.** Given a quad. ABCD in which  $AB = BC = CD = DA$  and O is a point within it such that  $OB = OD$ .

To prove  $\angle AOB + \angle COB = 180^\circ$

Proof In  $\triangle OAB$  and  $\triangle OAD$ , we have

$$AB = AD \text{ (given), } OA = OA$$

(common) and  $OB = OD$  (given)

$$\therefore \triangle OAB \cong \triangle OAD$$

$$\therefore \angle AOB = \angle AOD \quad \dots(i) \text{ (c.p.c.t.)}$$

Similarly,  $\triangle OBC \cong \triangle ODC$

$$\therefore \angle COB = \angle COD \quad \dots(ii)$$

$$\begin{aligned} \text{Now, } \angle AOB + \angle COB + \angle COD + \angle AOD \\ = 360^\circ \quad [\angle \text{ at a point}] \end{aligned}$$

$$\Rightarrow 2(\angle AOB + \angle COB) = 360^\circ$$

$$\Rightarrow \angle AOB + \angle COB = 180^\circ$$

**Ex.10** In figure AN and CP are perpendiculars to the diagonal BD of a parallelogram ABCD. Prove that :

$$(i) \triangle ADN \cong \triangle CBP \quad (ii) AN = CP$$

**Sol.** Since ABCD is a parallelogram.

$$\therefore AD \parallel BC$$

Now,  $AD \parallel BC$  and transversal BD intersects them at B and D.

$$\therefore \angle 1 = \angle 2$$

[ $\because$  Alternate interior angles are equal]

Now, in  $\triangle s$  ADN and CBP, we have

$$\angle 1 = \angle 2$$

$$\angle AND = \angle CPD \text{ and } AD = BC$$

[ $\because$  Opposite sides of a  $\parallel^m$  are equal]

So, by AAS criterion of congruence

$$\triangle ADN \cong \triangle CBP$$

$$AN = CP$$

[ $\because$  Corresponding parts of congruent triangles are equal]

**Ex.11** In figure, ABCD is a trapezium such that

$$AB \parallel CD \text{ and } AD = BC.$$

$BE \parallel AD$  and BE meets BC at E.

Show that (i) ABED is a parallelogram.

$$(ii) \angle A + \angle C = \angle B + \angle D = 180^\circ.$$

**Sol.** Here,  $AB \parallel CD$  (Given)

$$\Rightarrow AB \parallel DE \quad \dots(1)$$

$$\text{Also, } BE \parallel AD \text{ (Given)} \quad \dots(2)$$

From (1) and (2),

ABED is a parallelogram

$$\Rightarrow AD = BE \quad \dots(3)$$

$$\text{Also, } AD = BC \text{ (Given)} \quad \dots(4)$$

From (3) and (4),

$$BE = BC$$

$$\Rightarrow \angle BEC = \angle BCE \quad \dots(5)$$

$$\text{Also, } \angle BAD = \angle BED$$

(opposite angles of parallelogram ABED)

$$\text{i.e., } \angle BED = \angle BAD \quad \dots(6)$$

Now,  $\angle BED + \angle BEC = 180^\circ$  (Linear pair of angles)

$$\Rightarrow \angle BAD + \angle BCE = 180^\circ$$

By (5) and (6)

$$\Rightarrow \angle A + \angle C = 180^\circ$$

Similarly,  $\angle B + \angle D = 180^\circ$

**Ex.12** In figure ABCD is a parallelogram and  $\angle DAB = 60^\circ$ . If the bisectors AP and BP of angles A and B respectively, meet at P on CD, prove that P is the mid-point of CD.

**Sol.** We have,  $\angle DAB = 60^\circ$

$$\angle A + \angle B = 180^\circ$$

$$\therefore 60^\circ + \angle B = 180^\circ \Rightarrow \angle B = 120^\circ$$

Now,  $AB \parallel DC$  and transversal AP intersects them.

$$\therefore \angle PAB = \angle APD$$

$$\Rightarrow \angle APD = 30^\circ \quad [\because \angle PAB = 30^\circ]$$

Thus, in  $\triangle APD$ , we have

$$\angle PAD = \angle APD \quad [\text{Each equal to } 30^\circ]$$

$$\Rightarrow AD = PD \quad \dots (i)$$

$[\because \text{Angles opposite to equal sides are equal}]$

Since BP is the bisector of  $\angle B$ . Therefore,

$$\angle ABP = \angle PBC = 60^\circ$$

Now,  $AB \parallel DC$  and transversal BP intersects them.

$$\therefore \angle CPB = \angle ABP$$

$$\Rightarrow \angle CPB = 60^\circ \quad [\because \angle ABP = 60^\circ]$$

Thus, in  $\triangle CBP$ , we have

$$\angle CBP = \angle CPB \quad [\text{Each equal to } 60^\circ]$$

$$\Rightarrow CP = BC$$

$\therefore [\text{Sides opp. to equal angles are equal}]$

$$\Rightarrow CP = AD \quad \dots (ii)$$

$$[\because ABCD \text{ is a } \parallel\text{gm} \therefore AD = BC]$$

From (i) and (ii), we get

$$PD = CP$$

$\Rightarrow P$  is the mid point of CD.

- ◆ A quadrilateral is a parallelogram if its opposite sides are equal.
- ◆ A quadrilateral is a parallelogram if its opposite angles are equal.
- ◆ If the diagonals of a quadrilateral bisect each other, then the quadrilateral is a parallelogram.
- ◆ A quadrilateral is a parallelogram, if its one pair of opposite sides are equal and parallel.

**Ex.13** Prove that the line segments joining the mid-point of the sides of a quadrilateral forms a parallelogram.

**Sol.** Points E, F, G and H are the mid-points of the sides AB, BC, CD and DA respectively, of the quadrilateral ABCD. We have to prove that EFGH is a parallelogram.

Join the diagonal AC of the quadrilateral ABCD.

Now, in  $\triangle ABC$ , we have E and F mid-points of the sides BA and BC.

$$\Rightarrow EF \parallel AC$$

$$\text{and } EF = \frac{1}{2} AC \quad \dots (1)$$

Similarly, from  $\triangle ADC$ , we have

$$GH \parallel AC$$

$$\text{and } GH = \frac{1}{2} AC \quad \dots (2)$$

Then from (1) and (2), we have

$$EF \parallel GH$$

$$\text{and } EF = GH$$

This proves that EFGH is a parallelogram.

**Ex.14** In figure ABCD is a parallelogram and X, Y are the mid-points of sides AB and DC respectively. Show that AXCY is a parallelogram.

**Sol.** Since X and Y are the mid-points of AB and DC respectively. Therefore,

$$AX = \frac{1}{2} AB \text{ and } CY = \frac{1}{2} DC \quad \dots (i)$$

$$\text{But, } AB = DC \quad [\because ABCD \text{ is a } \parallel\text{gm}]$$

$$\Rightarrow \frac{1}{2} AB = \frac{1}{2} DC$$

$$\Rightarrow AX = CY \quad \dots (ii)$$

Also,  $AB \parallel DC$

$$\Rightarrow AX \parallel YC \quad \dots (iii)$$

Thus, in quadrilateral AXCY, we have

$$AX \parallel YC \text{ and } AX = YC$$

[From (ii) and (iii)]

Hence, quadrilateral AXCY is a parallelogram.

**Ex.15** Prove that the line segments joining the mid-points of the sides of a rectangle forms a rhombus.

**Sol.** P, Q, R and S are the mid-points of the sides AB, BC, CD and DA of the rectangle ABCD.

$$\text{Here, } AC = BD \quad (\because \triangle ABC \cong \triangle BAD)$$

$$\text{Now, } SR \parallel AC \text{ and } SR = \frac{1}{2} AC$$

$$\text{and } PQ \parallel AC \text{ and } PQ = \frac{1}{2} AC$$

$$\Rightarrow SR \parallel PQ \text{ and } SR = PQ = \frac{1}{2} AC$$

$$\text{Similarly, } PS \parallel QR \text{ and } PS = QR = \frac{1}{2} BD$$

$$\Rightarrow SR \parallel PQ, PS \parallel QR$$

$$\text{and } SR = PQ = PS = QR \quad (\because AC = BD)$$

PQRS is a rhombus.

**Ex.16** In figure ABCD is a parallelogram and X and Y are points on the diagonal BD such that  $DX = BY$ . Prove that

(i) AXCY is a parallelogram

(ii)  $AX = CY, AY = CX$

(iii)  $\triangle AYB \cong \triangle CXD$

**Sol.** Given : ABCD is a parallelogram. X and Y are points on the diagonal BD such that  $DX = BY$

To Prove :

(i) AXCY is a parallelogram

(ii)  $AX = CY, AY = CX$

(iii)  $\triangle AYB \cong \triangle CXD$

Construction : join AC to meet BD at O.

Proof :

(i) We know that the diagonals of a parallelogram bisect each other. Therefore, AC and BD bisect each other at O.

$$\therefore OB = OD$$

$$\text{But, } BY = DX$$

$$\therefore OB - BY = OD - DX$$

$$\Rightarrow OY = OX$$

Thus, in quadrilateral AXCY diagonals AC and XY are such that  $OX = OY$  and  $OA = OC$  i.e. the diagonals AC and XY bisect each other.

Hence, AXCY is a parallelogram.

(ii) Since AXCY is a parallelogram

$$\therefore AX = CY \text{ and } AY = CX$$

(iii) In triangles AYB and CXD, we have

$$AY = CX \quad [\text{From (ii)}]$$

$$AB = CD$$

$$[\because ABCD \text{ is a parallelogram}]$$

$$BY = DX \quad [\text{Given}]$$

So, by SSS-criterion of congruence, we have

$$\triangle AYB \cong \triangle CXD$$

**Ex.17** In fig. ABC is an isosceles triangle in which  $AB = AC$ .  $CP \parallel AB$  and  $AP$  is the bisector of exterior  $\angle CAD$  of  $\triangle ABC$ . Prove that  $\angle PAC = \angle BCA$  and  $ABCP$  is a parallelogram.

**Sol.** Given : An isosceles  $\triangle ABC$  having  $AB = AC$ .  $AP$  is the bisector of ext  $\angle CAD$  and  $CP \parallel AB$ .

To Prove :  $\angle PAC = \angle BCA$  and  $ABCP$

Proof : In  $\triangle ABC$ , we have

$$\begin{aligned} AB &= AC && \text{[Given]} \\ \Rightarrow \angle 1 &= \angle 2 && \dots (i) \end{aligned}$$

[ $\because$  Angles opposite to equal sides in a  $\triangle$  are equal]

Now, in  $\triangle ABC$ , we have

$$\text{ext } \angle CAD = \angle 1 + \angle 2$$

[ $\because$  An exterior angle is equal to the sum of two opposite interior angles]

$$\Rightarrow \text{ext } \angle CAD = 2\angle 2 \quad [\because \angle 1 = \angle 2 \text{ (from (i))}]$$

$$\Rightarrow 2\angle 3 = 2\angle 2$$

$$[\because AP \text{ is the bisector of ext. } \angle CAD \therefore \angle CAD = 2\angle 3]$$

$$\Rightarrow \angle 3 = \angle 2$$

Thus,  $AC$  intersects lines  $AP$  and  $BC$  at  $A$  and  $C$  respectively such that  $\angle 3 = \angle 2$  i.e., alternate interior angles are equal. Therefore,

$$AP \parallel BC.$$

$$\text{But, } CP \parallel AB \quad \text{[Given]}$$

Thus,  $ABCP$  is a quadrilateral such that  $AP \parallel BC$  and  $CP \parallel AB$ . Hence,  $ABCP$  is a parallelogram.

**Ex.18** In the given figure,  $ABCD$  is a square and  $\angle PQR = 90^\circ$ . If  $PB = QC = DR$ , prove that

(i)  $QB = RC$ , (ii)  $PQ = QR$ , (iii)  $\angle QPR = 45^\circ$ .

**Sol.**  $BC = DC$ ,  $CQ = DR \Rightarrow BC - CQ = DC - DR$

$$\Rightarrow QB = RC$$

$$\text{From } \triangle CQR, \angle RQB = \angle QCR + \angle QRC$$

$$\Rightarrow \angle RQP + \angle PQB = 90^\circ + \angle QRC$$

$$\Rightarrow 90^\circ + \angle PQB = 90^\circ + \angle QRC$$

Now,  $\triangle RCQ \cong \triangle QBP$  and therefore,

$$QR = PQ$$

$$PQ = QR \Rightarrow \angle QPR = \angle PRQ$$

$$\text{But, } \angle QPR + \angle PRQ = 90^\circ.$$

$$\text{So, } \angle QPR = 45^\circ$$

- ◆ Each of the four angles of a rectangle is a right angle.
- ◆ Each of the four sides of a rhombus is of the same length.
- ◆ Each of the angles of a square is a right angle and each of the four sides is of the same length.
- ◆ The diagonals of a rectangle are of equal length.
- ◆ If the two diagonals of a parallelogram are equal, it is a rectangle.
- ◆ The diagonals of a rhombus are perpendicular to each other.
- ◆ If the diagonals of a parallelogram are perpendicular, then it is a rhombus.
- ◆ The diagonals of a square are equal and perpendicular to each other.
- ◆ If the diagonals of a parallelogram are equal and intersect at right angles then the parallelogram is a square.

### ❖ EXAMPLES ❖

**Ex.19** Prove that in a parallelogram

- (i) opposite sides are equal
- (ii) opposite angles are equal
- (iii) each diagonal bisects the parallelogram

**Sol.** Given : A ||gm ABCD in which  $AB \parallel DC$  and  $AD \parallel BC$ .

To prove (i)  $AB = CD$  and  $BC = AD$ ;

(ii)  $\angle B = \angle D$  and  $\angle A = \angle C$ ,

(iii)  $\triangle ABC = \triangle CDA$  and  $\triangle ABD = \triangle CDB$

Construction join A and C.

In  $\triangle ABC$  and  $CDA$ , we have,

$$\angle 1 = \angle 2$$

[Alt. int.  $\angle$ , as  $AB \parallel DC$  and  $CA$  cuts them]

$$\angle 3 = \angle 4$$

[Alt. int.  $\angle$ , as  $BC \parallel AD$  and  $CA$  cuts them]

$AC = CA$  (common)

$\therefore \triangle ABC \cong \triangle CDA$  [AAS-criterial]

(i)  $\triangle ABC \cong \triangle CDA$  (proved)

$\therefore AB = CD$  and  $BC = AD$  (c.p.c.t.)

(ii)  $\triangle ABC \cong \triangle CDA$  (proved)

$\therefore \angle B = \angle D$  (c.p.c.t.)

Also,  $\angle 1 = \angle 2$  and  $\angle 3 = \angle 4$

$$\angle 1 + \angle 4 = \angle 2 + \angle 3 \Rightarrow \angle A = \angle C$$

Hence,  $\angle B = \angle D$  and  $\angle A = \angle C$

(iii) Since  $\triangle ABC \cong \triangle CDA$  and congruent triangles are equal in area,

So we have  $\triangle ABC = \triangle CDA$

Similarly,  $\triangle ABD = \triangle CDB$

**Ex.20** If the diagonals of a parallelogram are perpendicular to each other, prove that it is a rhombus.

**Sol.** Since the diagonals of a ||gm bisect each other,

we have,  $OA = OC$  and  $OB = OD$ .

Now, in  $\triangle AOD$  and  $COD$ , we have

$$OA = OC, \angle AOD = \angle COD = 90^\circ$$

and  $OD$  is common

$$\therefore \triangle AOD \cong \triangle COD$$

$$\therefore AD = CD \text{ (c.p.c.t.)}$$

Now,  $AB = CD$  and  $AD = BC$

(opp. sides of a ||gm)

and  $AD = CD$  (proved)

$$\therefore AB = CD = AD = BC$$

Hence, ABCD is a rhombus.

**Ex.21** PQRS is a square. Determine  $\angle SRP$ .

**Sol.** PQRS is a square.

$$\therefore PS = SR \text{ and } \angle PSR = 90^\circ$$

Now, in  $\triangle PSR$ , we have

$$PS = SR$$

$$\Rightarrow \angle 1 = \angle 2 \quad \left[ \begin{array}{l} \because \text{Angles opp. to} \\ \text{equal sides are equal} \end{array} \right]$$

$$\text{But, } \angle 1 + \angle 2 + \angle PSR = 180^\circ$$

$$\therefore 2\angle 1 + 90^\circ = 180^\circ \quad [\because \angle PSR = 90^\circ]$$

$$\Rightarrow 2\angle 1 = 90^\circ$$

$$\Rightarrow \angle 1 = 45^\circ$$

**Ex.22** In the adjoining figure, ABCD is a rhombus.  
If  $\angle A = 70^\circ$ , find  $\angle CDB$

**Sol.**

We have  $\angle C = \angle A = 70^\circ$   
(opposite  $\angle$  of a ||gm)

Let  $\angle CDB = x^\circ$

In  $\triangle CDB$ , we have

$$CD = CB \Rightarrow \angle CBD = \angle CDB = x^\circ$$

$$\therefore \angle CDB + \angle CBD + \angle DCB = 180^\circ$$

(angles of a triangle)

$$\Rightarrow x^\circ + x^\circ + 70^\circ = 180^\circ$$

$$\Rightarrow 2x = 110, \text{ i.e., } x = 55$$

Hence,  $\angle CDB = 55^\circ$

**Ex.23** ABCD is a rhombus with  $\angle ABC = 56^\circ$ .  
Determine  $\angle ACD$ .

**Sol.** ABCD is a parallelogram

$$\Rightarrow \angle ABC = \angle ADC$$

$$\Rightarrow \angle ADC = 56^\circ \quad [\because \angle ABC = 56^\circ \text{ (Given)}]$$

$$\Rightarrow \angle ODC = 28^\circ \quad [\because \angle ODC = \frac{1}{2} \angle ADC]$$

Now,  $\triangle OCD$  we have,

$$\angle OCD + \angle ODC + \angle COD = 180^\circ$$

$$\Rightarrow \angle OCD + 28^\circ + 90^\circ = 180^\circ$$

$$\Rightarrow \angle OCD = 62^\circ \Rightarrow \angle ACD = 62^\circ.$$

- ◆ The line segment joining the mid-points of any two sides of a triangle is parallel to the third side and equal to half of it.
- ◆ The line drawn through the mid-point of one side of a triangle, parallel to another side, intersects the third side at its mid-point.

**Ex.24** Prove that the line segment joining the mid-points of the diagonals of a trapezium is parallel to each of the parallel sides and is equal to half the difference of these sides.

**Sol.** Given : A trapezium ABCD in which  $AB \parallel DC$  and P and Q are the mid-points of its diagonals AC and BD respectively.

To Prove : (i)  $PQ \parallel AB$  or  $DC$

$$(ii) PQ = \frac{1}{2} (AB - DC)$$

Construction : Join DP and produce DP to meet AB in R.

Proof : Since  $AB \parallel DC$  and transversal AC cuts them at A and C respectively.

$$\angle 1 = \angle 2 \quad \dots (i)$$

[ $\therefore$  Alternate angles are equal]

Now, in  $\triangle APR$  and  $DPC$ , we have

$$\angle 1 = \angle 2 \quad [\text{From (i)}]$$

$$AP = CP \quad [\because P \text{ is the mid-point of } AC]$$

and,  $\angle 3 = \angle 4$  [Vertically opposite angles]

So, by ASA criterion of congruence

$$\triangle APR \cong \triangle DPC$$

$$\Rightarrow AR = DC \text{ and } PR = DP \quad \dots (ii)$$

[ $\therefore$  Corresponding parts of  
congruent triangles are equal]

In  $\triangle DRB$ , P and Q are the mid-points of sides DR and DB respectively.

$$\therefore PQ \parallel RB$$

$$\Rightarrow PQ \parallel AB \quad [\because RB \text{ is a part of } AB]$$

$$\Rightarrow PQ \parallel AB \text{ and } DC \quad [\because AB \parallel DC \text{ (Given)}]$$

This proves (i).

Again, P and Q are the mid-points of sides DR and DB respectively in  $\triangle DRB$ .

$$\therefore PQ = \frac{1}{2} RB \Rightarrow PQ = \frac{1}{2} (AB - AR)$$

$$\Rightarrow PQ = \frac{1}{2} (AB - DC) \quad [\text{From (ii), } AR = DC]$$

This proves (ii).

- ◆ A diagonal of a parallelogram divides it into two triangles of equal area.
- ◆ For each base of a parallelogram, the corresponding altitude is the line segment from a point on the base, perpendicular to the line containing the opposite side.
- ◆ Parallelograms on the same base and between the same parallels are equal in area.
- ◆ A parallelogram and a rectangle on the same base and between the same parallels are equal in area.
- ◆ The area of a parallelogram is the product of its base and the corresponding altitude.
- ◆ Parallelograms on equal bases and between the same parallels are equal in area.

### ❖ EXAMPLES ❖

**Ex.25** In the adjoining figure, ABCD is parallelogram and X, Y are the points on diagonal BD such that  $DX = BY$ . Prove that CXAY is a parallelogram.

**Sol.** Join AC, meeting BD at O.

Since the diagonals of a parallelogram bisect each other, we have  $OA = OC$  and  $OD = OB$ .

Now,  $OD = OB$  and  $DX = BY$

$$\Rightarrow OD - DX = OB - BY \Rightarrow OX = OY$$

Now,  $OA = OC$  and  $OX = OY$

$\therefore$  CXAY is a quadrilateral whose diagonals bisect each other.

$\therefore$  CXAY is a ||gm

**Ex.26** Prove that the four triangles formed by joining in pairs, the mid-points of three sides of a triangle, are concurrent to each other.

**Sol.** Given : A triangle ABC and D,E,F are the mid-points of sides BC, CA and AB respectively.

To Prove :

$$\Delta AFE \cong \Delta FBD \cong \Delta EDC \cong \Delta DEF.$$

Proof : Since the segment joining the mid-points of the sides of a triangle is half of the third side. Therefore,

$$DE = \frac{1}{2} AB \Rightarrow DE = AF = BF \quad \dots (i)$$

$$EF = \frac{1}{2} BC \Rightarrow EF = BD = CD \quad \dots (ii)$$

$$DF = \frac{1}{2} AC \Rightarrow DF = AE = EC \quad \dots (iii)$$

Now, in  $\Delta s$  DEF and AFE, we have

$$DE = AF \quad [\text{From (i)}]$$

$$DF = AE \quad [\text{From (ii)}]$$

$$\text{and, } EF = FE \quad [\text{Common}]$$

So, by SSS criterion of congruence,

$$\Delta DEF \cong \Delta AFE$$

$$\text{Similarly, } \Delta DEF \cong \Delta FBD \text{ and } \Delta DEF \cong \Delta EDC$$

$$\text{Hence, } \Delta AFE \cong \Delta FBD \cong \Delta EDC \cong \Delta DEF$$

**Ex.27** In fig, AD is the median and  $DE \parallel AB$ . Prove that BE is the median.

**Sol.** In order to prove that BE is the median, it is sufficient to show that E is the mid-point of AC.

Now, AD is the median in  $\Delta ABC$

$$\Rightarrow D \text{ is the mid-point of } BC.$$

Since DE is a line drawn through the mid-point of side BC of  $\Delta ABC$  and is parallel to AB (given). Therefore, E is the mid-point of AC. Hence, BE is the median of  $\Delta ABC$ .

**Ex.28** Let ABC be an isosceles triangle with  $AB = AC$  and let D, E, F be the mid-points of BC, CA and AB respectively. Show that  $AD \perp FE$  and AD is bisected by FE.

**Sol.** Given : An isosceles triangle ABC with D, E and F as the mid-points of sides BC, CA and AB respectively such that  $AB = AC$ . AD intersects FE at O.

To Prove :  $AD \perp FE$  and AD is bisected by FE.

Constructon : Join DE and DF.

Proof : Since the segment joining the mid-points of two sides of a triangle is parallel to third side and is half of it. Therefore,

$$DE \parallel AB \text{ and } DE = \frac{1}{2} AB$$

$$\text{Also, } DF \parallel AC \text{ and } DF = \frac{1}{2} AC$$

But,  $AB = AC$  [Given]

$$\Rightarrow \frac{1}{2} AB = \frac{1}{2} AC \Rightarrow DE = DF \quad \dots (i)$$

$$\text{Now, } DE = \frac{1}{2} AB \Rightarrow DE = AF \quad \dots (ii)$$

$$\text{and, } DF = \frac{1}{2} AC \Rightarrow DF = AE \quad \dots (iii)$$

From (i), (ii) and (iii) we have

$$DE = AE = AF = DF$$

$\Rightarrow$  DEAF is a rhombus.

$\Rightarrow$  Diagonals AD and FE bisect each other at right angle.

$AD \perp FE$  and AD is bisected by FE.

**Ex.29** ABCD is a parallelogram. P is a point on AD such that  $AP = \frac{1}{3} AD$  and Q is a point on BC such that  $CQ = \frac{1}{3} BP$ . Prove that AQCP is a parallelogram.

**Sol.** ABCD is a parallelogram.

$$\Rightarrow AD = BC \text{ and } AD \parallel BC$$

$$\Rightarrow \frac{1}{3} AD = \frac{1}{3} BC \text{ and } AD \parallel BC$$

$$\Rightarrow AP = CQ \text{ and } AP \parallel CQ$$

Thus, APCQ is a quadrilateral such that one pair of opposite side AP and CQ are parallel and equal.

Hence, APCQ is a parallelogram.

**Ex.30** In fig. D, E and F are, respectively the mid-points of sides BC, CA and AB of an equilateral triangle ABC. Prove that DEF is also an equilateral triangle.

**Sol.** Since the segment joining the mid-points of two sides of a triangle is half of the third side. Therefore, D and E are mid-points of BC and AC respectively.

$$\Rightarrow DE = \frac{1}{2} AB \quad \dots (i)$$

E and F are the mid-points of AC and AB respectively.

$$\therefore EF = \frac{1}{2} BC \quad \dots (ii)$$

F and D are the mid-points AB and BC respectively.

$$\Rightarrow FD = \frac{1}{2} AC$$

Now,  $\triangle ABC$  is an equilateral triangle

$$\Rightarrow AB = BC = CA \Rightarrow \frac{1}{2} AB = \frac{1}{2} BC = \frac{1}{2} CA$$

$$\Rightarrow DE = EF = FD$$

[Using (i), (ii) and (iii)]

Hence,  $\triangle DEF$  is an equilateral triangle.

**Ex.31** P, Q and R are, respectively, the mid-points of sides BC, CA and AB of a triangle ABC. PR and BQ meet at X. CR and PQ meet at Y.

Prove that  $XY = \frac{1}{4}BC$

**Sol.** Given : A  $\triangle ABC$  with P, Q and R as the mid-points of BC, CA and AB respectively. PR and BQ meet at X and CR and PQ meet at Y.

Construction : Join "X and Y".

Proof: Since the line segment joining the mid-points of two sides of a triangle is parallel to the third side and is half of it. Therefore, Q and R are mid-points of AC and AB respectively.

$$\therefore RQ \parallel BC \text{ and } RQ = \frac{1}{2} BC \quad \dots (i)$$

$$\left[ \because P \text{ is the mid-point of } BC \therefore \frac{1}{2}BC = BP \right]$$

$$\Rightarrow RQ \parallel BP \text{ and } RQ = BP$$

$\Rightarrow$  BPQR is a parallelogram.

Since the diagonals of a parallelogram bisect each other.

$\therefore$  X is the mid-point of PQ.

$$\left[ \because X \text{ is the point of intersection of diagonals BQ and PR of } \parallel^{\text{gm}} \text{BPQR} \right]$$

Similarly, Y is the mid-point of PQ.

Now, consider  $\triangle PQR$ . XY is the line segment joining the mid-points of sides PR and PQ.

$$\therefore XY = \frac{1}{2} RQ \quad \dots (i)$$

$$\text{But } RQ = \frac{1}{2} BC \quad [\text{From (i)}]$$

$$\text{Hence, } XY = \frac{1}{4} BC.$$

**Ex.32** Show that the quadrilateral, formed by joining the mid-points of the sides of a square, is also a square.

**Sol.** Given : A square ABCD in which P, Q, R, S are the mid-points of sides AB, BC, CD, DA respectively. PQ, QR, RS and SP are joined.

To Prove : PQRS is a square.

Construction : Join AC and BD.

Proof : In  $\triangle ABC$ , P and Q are the mid-points of sides AB and BC respectively.

$$\therefore PQ \parallel AC \text{ and } PQ = \frac{1}{2} AC \quad \dots (i)$$

In  $\triangle ADC$ , R and S are the mid-points of CD and AD respectively.

$$\therefore RS \parallel AC \text{ and } RS = \frac{1}{2} AC \quad \dots (ii)$$

From (i) and (ii), we have

$$PQ \parallel RS \text{ and } PQ = RS \quad \dots (iii)$$

Thus, in quadrilateral PQRS one pair of opposite sides are equal and parallel.

Hence, PQRS is a parallelogram.

Now, in  $\triangle PBQ$  and  $\triangle RCQ$ , we have

$$PB = RC$$

$$\left[ \because ABCD, \text{ is a square } \therefore AB = BC = CD = DA \right]$$

$$\Rightarrow \frac{1}{2} AB = \frac{1}{2} CD \text{ and } \frac{1}{2} AB = \frac{1}{2} BC$$

$$BQ = CQ \quad [\Rightarrow PB = CR \text{ and } BQ = CQ]$$

$$\text{and } \angle PBQ = \angle RCQ \quad [\text{Each equal to } 90^\circ]$$

So, by SAS criterion of congruence

$$\triangle PBQ \cong \triangle RCQ$$

$$\Rightarrow PQ = QR \quad \dots (iv)$$

$[\because \text{Corresponding parts of congruent } \triangle \text{ s are equal}]$

From (iii) and (iv), we have

$$PQ = QR = RS$$

But, PQRS is a  $\square$ .

$$QR = PS$$

$$\text{So, } PQ = QR = RS = PS \quad \dots(v)$$

$$\text{Now, } PQ \parallel AC \quad [\text{From (i)}]$$

$$\Rightarrow PM \parallel NO \quad \dots(vi)$$

Since P and S are the mid-points of AB and AD respectively.

$$PS \parallel BD$$

$$\Rightarrow PM \parallel MO \quad \dots(vii)$$

Thus, in quadrilateral PMON, we have

$$PM \parallel NO \quad [\text{From (vi)}]$$

$$PN \parallel MO \quad [\text{From (vii)}]$$

So, PMON is a parallelogram.

$$\Rightarrow \angle MPN = \angle MON$$

$$\Rightarrow \angle MPN = \angle BOA \quad [\because \angle MON = \angle BOA]$$

$$\Rightarrow \angle MPN = 90^\circ$$

$$\left[ \begin{array}{l} \because \text{Diagonals of square are } \perp \\ \therefore AC \perp BD \Rightarrow \angle BOA = 90^\circ \end{array} \right]$$

$$\Rightarrow \angle QPS = 90^\circ$$

Thus, PQRS is a quadrilateral such that  $PQ = QR = RS = SP$  and  $\angle QPS = 90^\circ$ .

Hence, PQRS is a square.

**Ex.33**  $\triangle ABC$  is a triangle right angled at B ; and P is the mid-point of AC. Prove that  $PB = PA = \frac{1}{2} AC$ .

**Sol.** Given :  $\triangle ABC$  right angled at B, P is the mid-point of AC.

$$\text{To Prove : } PB = PA = \frac{1}{2} AC.$$

Construction : Through P draw  $PQ \parallel BC$  meeting AB at Q.

Proof : Since  $PQ \parallel BC$ . Therefore,

$$\angle AQP = \angle ABC \quad [\text{Corresponding angles}]$$

$$\Rightarrow \angle AQP = 90^\circ$$

$$[\because \angle ABC = 90^\circ]$$

$$\text{But, } \angle AQP + \angle BQP = 180^\circ$$

$$[\because \angle AQP \text{ \& } \angle BQP \text{ are angles of a linear pair}]$$

$$\therefore 90^\circ + \angle BQP = 180^\circ$$

$$\Rightarrow \angle BQP = 90^\circ$$

$$\text{Thus, } \angle AQP = \angle BQP = 90^\circ$$

Now, in  $\triangle ABC$ , P is the mid-point of AC and  $PQ \parallel BC$ . Therefore, Q is the mid-point of AB i.e,  $AQ = BQ$ .

Consider now  $\triangle APQ$  and  $\triangle BPQ$ .

$$\text{we have, } AQ = BQ \quad [\text{Proved above}]$$

$$\angle AQP = \angle BQP \quad [\text{From (i)}]$$

$$\text{and, } PQ = PQ$$

So, by SAS criterion of congruence

$$\triangle APQ \cong \triangle BPQ$$

$$\Rightarrow PA = PB$$

Also,

$$PS = \frac{1}{2} AC, \text{ since P is the mid-point of AC}$$

$$\text{Hence, } PA = PB = \frac{1}{2} AC.$$

**Ex.34** Show that the quadrilateral formed by joining the mid-points of the consecutive sides of a rectangle is a rhombus.

**Sol.** Given : A rectangle ABCD in which P, Q, R and S are the mid-points of sides AB, BC, CD and DA respectively. PQ, QR, RS and SP are joined.

To Prove : PQRS is rhombus.

Construction : Join AC.

Proof : In  $\triangle ABC$ , P and Q are the mid-points of sides AB and BC respectively.

$$\therefore PQ \parallel AC \text{ and } PQ = \frac{1}{2} AC \quad \dots (i)$$

In  $\triangle ADC$ , R and S are the mid-points of CD and AD respectively.

$$\therefore SR \parallel AC \text{ and } SR = \frac{1}{2} AC \quad \dots (ii)$$

From (i) and (ii), we get

$$PQ \parallel SR \text{ and } PQ = SR \quad \dots (iii)$$

$\Rightarrow$  PQRS is a parallelogram.

Now, ABCD is a rectangle.

$$\Rightarrow AD = BC \Rightarrow \frac{1}{2} AD = \frac{1}{2} BC$$

$$\Rightarrow AS = BQ \quad \dots (iv)$$

In  $\triangle APS$  and  $\triangle BPQ$ , we have

$$AP = BP \quad [\because P \text{ is the mid-point of } AB]$$

$$\angle PAS = \angle PBQ \quad [\text{Each equal to } 90^\circ]$$

$$\text{and, } AS = BQ \quad [\text{From (iv)}]$$

So, by SAS criterion of congruence

$$\triangle APS \cong \triangle BPQ$$

$$PS = PQ \quad \dots (v)$$

$[\because \text{Corresponding parts of congruent triangles are equal}]$

From (iii) and (v), we obtain that PQRS is a parallelogram such that  $PS = PQ$  i.e., two adjacent sides are equal.

Hence, PQRS is a rhombus.

## **IMPORTANT POINTS TO BE REMEMBERED**

1. Sum of the angles of a quadrilateral is  $360^\circ$ .
2. A diagonal of a parallelogram divides it into two congruent triangles.
3. Two opposite angles of a parallelogram are equal.
4. The diagonals of a parallelogram bisect each other.
5. In a parallelogram, the bisectors of any two consecutive angles intersect at right angle.
6. If a diagonal of a parallelogram bisects one of the angles of the parallelogram it also bisects the second angle.
7. The angles bisectors of a parallelogram form a rectangle.
8. A quadrilateral is a parallelogram if its opposite sides are equal.
9. A quadrilateral is a parallelogram iff its opposite angles are equal.
10. The diagonals of a quadrilateral bisect each other, iff it is a parallelogram.
11. A quadrilateral is a parallelogram if its one pair of opposite sides are equal and parallel.
12. Each of the four angles of a rectangle is a right angle.
13. Each of the four sides of a rhombus is of the same length.
14. The diagonals of a rectangle are of equal length.
15. Diagonals of a parallelogram are equal if and only if it is a rectangle.
16. The diagonals of a rhombus are perpendicular to each other.
17. Diagonals of a parallelogram are perpendicular if and only if it is a rhombus.
18. The diagonals of a square are equal and perpendicular to each other.
19. If the diagonals of a parallelogram are equal and intersect at right angle, then it is a square.
20. The line segment joining the mid-points of any two sides of a triangle is parallel to the third side and equal to half of it.
21. A line through the mid-point of a side of a triangle parallel to another side bisects the third side.
22. The quadrilateral formed by joining the mid-points of the sides of a quadrilateral, in order, is a parallelogram.
