

# Basic Inorganic Nomenclature

## Section (A) : Oxidation number

### Th-1 Oxidation Number

- It is an imaginary or apparent charge developed over atom of an element when it goes from its elemental free state to combined state in molecules.
- It is calculated on the basis of an arbitrary set of rules.
- It is a relative charge in a particular bonded state.
- In order to keep track of electron-shifts in chemical reactions involving formation of compounds, a more practical method of using oxidation number has been developed.
- In this method, it is always assumed that there is a complete transfer of electron from a less electronegative atom to a more electronegative atom.

### Rules governing oxidation number

The following rules are helpful in calculating oxidation number of the elements in their different compounds. It is to be remembered that the basis of these rule is the electronegativity of the element.

- **Fluorine atom :**  
Fluorine is most electronegative atom (known). It always has oxidation number equal to  $-1$  in all its compounds
- **Oxygen atom :**  
In general and as well as in its oxides, oxygen atom has oxidation number equal to  $-2$ .  
**In case of**
  - peroxide (e.g.  $\text{H}_2\text{O}_2$ ,  $\text{Na}_2\text{O}_2$ ) is  $-1$ ,
  - super oxide (e.g.  $\text{KO}_2$ ) is  $-1/2$
  - ozonide (e.g.  $\text{KO}_3$ ) is  $-1/3$
  - in  $\text{OF}_2$  is  $+2$  & in  $\text{O}_2\text{F}_2$  is  $+1$
- **Hydrogen atom :**  
In general, H atom has oxidation number equal to  $+1$ . But in metallic hydrides (e.g.  $\text{NaH}$ ,  $\text{KH}$ ), it is  $-1$ .

### ● HALOGEN ATOM :

In general, all halogen atoms (Cl, Br, I) have oxidation number equal to  $-1$ .

But if halogen atom is attached with a more electronegative atom than halogen atom, then it will show positive oxidation numbers.

e.g.  $\overset{+5}{\text{K}}\overset{+5}{\text{ClO}}_3$ ,  $\overset{+5}{\text{H}}\overset{+5}{\text{IO}}_3$ ,  $\overset{+7}{\text{H}}\overset{+7}{\text{ClO}}_4$ ,  $\overset{+5}{\text{K}}\overset{+5}{\text{BrO}}_3$

### ● METALS :

(a) Alkali metal (Li, Na, K, Rb ..... ) always have oxidation number  $+1$ .

(b) Alkaline earth metal (Be, Mg, Ca ..... ) always have oxidation number  $+2$ .

(c) Aluminium always has  $+3$  oxidation number.

**Note :** Metal may have positive or zero oxidation number

- Oxidation number of an element in free state or in allotropic forms is always zero

e.g.  $\overset{0}{\text{O}}_2$ ,  $\overset{0}{\text{S}}_8$ ,  $\overset{0}{\text{P}}_4$ ,  $\overset{0}{\text{O}}_3$

- Sum of the oxidation numbers of atoms of all elements in a molecule is zero.
- Sum of the oxidation numbers of atoms of all elements in an ion is equal to the charge on the ion.
- If the group number of an element in modern periodic table is  $n$ , then its oxidation number may vary from

$(n - 10)$  to  $(n - 18)$

(but it is mainly applicable for p-block elements)

e.g. N-atom belongs to 15<sup>th</sup> group in the periodic table, therefore as per rule, its oxidation number may vary from  $-3$  to  $+5$ .

$\overset{-3}{\text{N}}\text{H}_3$ ,  $\overset{+2}{\text{N}}\text{O}$ ,  $\overset{+3}{\text{N}}_2\text{O}_3$ ,  $\overset{+4}{\text{N}}\text{O}_2$ ,  $\overset{+5}{\text{N}}_2\text{O}_5$

- The maximum possible oxidation number of any element in a compound is never more than the number of electrons in valence shell. (but it is mainly applicable for p-block elements)

**Table-1**  
**List of common oxidation state of an element of periodic table,**  
**which can be show in compound state**

1 H +1 −1												13	14	15	16	17	18 He
3 Li +1	3 Be +2											5 B +3 −3	6 C +4 +2 −4 etc.	7 N +5 +4 +3 +1 −3 0 etc.	8 O +2 − 1/2 −1 −2	9 F −1	10 Ne
11 Na +1	12 Mg +2											13 Al +3	14 Si +4 −4	15 P +5 +3 +1 −3	16 S +6 +4 +2 −2	17 Cl +7 +5 +3 +1 0 −1	18 Ar 0
19 K +1	20 Ca +2	3 21 Sc +2 +3	4 22 Ti +2 +3 +4	5 23 V +2 +3 +4 +5	6 24 Cr +2 +3 +4 +5 +6	7 25 Mn +2 +3 +4 +5 +6 +7	8 26 Fe +2 +3 +4 +5 +6	9 27 Co +2 +3 +4 +5	10 28 Ni +2 +3 +4	11 29 Cu +1 +2	12 30 Zn +2	31 Ga +3	32 Ge +4 −4	33 As +5 +3 −3	34 Se +6 +4 −2	35 Br +7 +5 +3 +1 −1	36 Kr +4 +2 0
37 Rb +1	38 Sr +2											49 In +3 +1	50 Sn +4 +2	51 Sb +5 +3 −3	52 Te +6 +4 −2	53 I +7 +5 +3 +1 0 −1	54 Xe +8 +6 +4 +2 0 0
55 Cs +1	56 Ba +2											81 Tl +3 +1	82 Pb +4 +2	83 Bi +5 +3	84 Po	85 At	86 Rn

- \* **Bold mark oxidation number are general stable oxidation number of an element in compound state.**

## Section (B) : Inorganic nomenclature

### Th-1 Elements

**General Rule :** The names of metals generally end with-ium or-um (examples are sodium, potassium, aluminum, and magnesium).

The exceptions are metals that were used and named in ancient times, such as iron, copper, and gold.

The names of nonmetals frequently end with-ine, -on, or -gen (such as iodine, argon, and oxygen.)

Given the names of the constituent elements and common ions, most of the common inorganic compounds can be named using the rules presented below.

### Th-2 Acids :

Acids are normally classified in two groups, hydracids and oxyacids

#### Hydracids :

Hydracids are acids which contain hydrogen and a non-metal, but no oxygen.

**General Rule :** The names of hydracids have the prefix hydro-(sometimes shortened to hydr-) and the suffix-ic attached to the stem based on the names of the constituent elements (other than hydrogen.)

For example, HCl (made of hydrogen and chlorine) is hydrochloric acid; HBr (made of hydrogen and bromine) is hydrobromic acid; HI (made of hydrogen and iodine) is hydroiodic acid; HCN (made of hydrogen, carbon and nitrogen) is hydrocyanic acid; and H<sub>2</sub>S (made of hydrogen and sulfur) is hydrosulfuric acid.

### Th-3 Cations (Positive ions)

#### Metal atoms with single positive charge

**Rule :** Names of positive ions end with-ium if the ion has only one oxidation state (Only one level of net charge). For example, the positive ion of sodium is Na<sup>+</sup> (sodium ion), and the positive ion of aluminium is Al<sup>3+</sup> (aluminium ion).

#### Metal atoms with more than one possible charges

**Rule :** If the cation has variable valency (charge), charge is specified in roman numerals in round brackets immediately after the name of metal atom. For example , Sn<sup>2+</sup> is written as tin (II) ion.

**Alternately, the less positive ion ends with -ous, and the more positive ion ends with -ic.** For instance, the two positive ions of copper are Cu<sup>+</sup> (cuprous) and Cu<sup>2+</sup> (cupric). The oxidation state of a positive ion can also be designated by placing a Roman numeral after the name of the elements. These positive ions of copper can also be written as copper(I) and copper(II), respectively.

Ions	Name
Cu <sup>+</sup>	cuprous ion
Cu <sup>2+</sup>	cupric ion
Sn <sup>2+</sup>	Stannous ion
Sn <sup>4+</sup>	Stannic ion
Fe <sup>3+</sup>	Ferric ion
Fe <sup>2+</sup>	Ferrous ion

#### General Rule-3

Suffix-ium is often used with cations containing non metals.

For example, the positive ion of ammonia is NH<sub>4</sub><sup>+</sup> (ammonium) and the positive ion of water (H<sub>2</sub>O) is H<sub>3</sub>O<sup>+</sup> or H<sup>+</sup> (hydronium).

#### Remember these names !

**NO<sub>2</sub><sup>+</sup> : nitronium**

**NO<sup>+</sup> : nitrosonium**

**H<sub>3</sub>O<sup>+</sup> : hydronium**

From NH<sub>3</sub> ammonia is derived NH<sub>4</sub><sup>+</sup> : ammonium.

Similarly.

N<sub>2</sub>H<sub>4</sub> : hydrazine → N<sub>2</sub>H<sub>5</sub><sup>+</sup> : hydrazinium

C<sub>6</sub>H<sub>5</sub>NH<sub>2</sub> : aniline → C<sub>6</sub>H<sub>5</sub>NH<sub>3</sub><sup>+</sup> : anilinium

C<sub>5</sub>H<sub>5</sub>N : pyridine → C<sub>5</sub>H<sub>5</sub>NH<sup>+</sup> : pyridinium

### Th-4 Anions (Negative Ions)

Anions can always be looked upon as ions derived from acids by removal of one or more protons. Accordingly, anions can be classified as follows :

### Anions derived from hydric acids

**Rule : Names of negative ions from hydric acids end in -ide.**

For example,  $\text{Cl}^-$  (chloride) from  $\text{HCl}$ , and  $\text{CN}^-$  (cyanide) from  $\text{HCN}$ . Following examples will give you a better insight in this nomenclature. It is also useful to remember them.

**Remember these names**

Anion	Name
$\text{H}^-$	Hydride ion
$\text{D}^-$	Deuteride ion
$\text{F}^-$	Fluoride ion
$\text{Cl}^-$	Chloride ion
$\text{Br}^-$	Bromide ion
$\text{I}^-$	Iodide ion
$\text{O}^{2-}$	Oxide ion
$\text{S}^{2-}$	Sulphide ion
$\text{Se}^{2-}$	Selenide ion
$\text{Te}^{2-}$	Telluride ion
$\text{N}^{3-}$	Nitride ion
$\text{P}^{3-}$	Phosphide ion
$\text{As}^{3-}$	Arsenide ion
$\text{Sb}^{3-}$	Antimonide ion
$\text{C}^{4-}$	Carbide ion
$\text{Si}^{4-}$	Silicide ion
$\text{B}^{3-}$	Boride ion

### Th-5 Oxoacids or Oxyacids

The acids which contain hydrogen, oxygen and a metal or non-metal.

In this case, more than one possibility arises due to the presence of different number of oxygen atoms. An example of such an oxoacid series is as follows:  $\text{HClO}$ ,  $\text{HClO}_2$ ,  $\text{HClO}_3$ ,  $\text{HClO}_4$ . All these contain same three elements but differ in the number of oxygen atoms present.

**General Rule-1 :**

If a class of acids contains only one member, its name is given the suffix -ic.

For example, hydrogen, carbon and oxygen combine to form only one acid i.e.  $\text{H}_2\text{CO}_3$ . It is called carbonic acid (carbonic acid.)

**General Rule-2 :**

If an acid series contains two acids, such as  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_3$ , the acid containing more oxygen atoms is given the suffix -ic, while the acid with fewer oxygen atoms is given the suffix -ous.

For example,  $\text{H}_2\text{SO}_4$  is sulphuric acid, and  $\text{H}_2\text{SO}_3$  is sulphurous acid.

Similarly,  $\text{HNO}_3$  is nitric acid and  $\text{HNO}_2$  is nitrous acid.

**General Rule-3 :**

The prefix ortho and meta have been used to distinguish acids differing in the 'content of water'

$(\text{H}_3\text{BO}_3)$  - orthoboric acid  $-\text{H}_2\text{O}$

$(\text{HBO}_2)_n$  - metaboric acid

**General Rule-4 :**

The prefix pyro has been used to designate an acid formed from two molecules of an ortho acid minus one molecule of water.

For example,  $\text{H}_4\text{P}_2\text{O}_7$  - pyro phosphoric acid

**General Rule-5 :**

The prefix peroxo indicates the substitution '-O-' by '-O-O-'

$\text{HNO}_4$  - peroxo nitric acid

$\text{H}_3\text{PO}_5$  - peroxo mono phosphoric acid

**General Rule-6 :**

Acid derived by oxoacids by replacement of oxygen by sulphur are called thio acids.

$\text{H}_2\text{S}_2\text{O}_2$  - thio sulphurous acid

$\text{H}_2\text{S}_2\text{O}_3$  - thio sulphuric acid

**Note :** when more than one oxygen atom can be replaced by sulphur the number of sulphur atom should generally indicated

$\text{H}_3\text{PO}_3\text{S}$  mono thio phosphoric acid

$\text{H}_3\text{PO}_2\text{S}_2$  Dithiophosphoric acid

In the case of an extensive acid series (such as  $\text{HClO}$ ,  $\text{HClO}_2$ ,  $\text{HClO}_3$ ,  $\text{HClO}_4$ ), the acid with the one oxygen atoms lesser than -ous acid is given the prefix hypo- and the suffix -ous, and the acid with the one oxygen atom more than the -ic acid is given the prefix per and a suffix -ic.

In the above example,  $\text{HClO}$  is hypochlorous acid  $\text{HClO}_2$  is chlorous acid,  $\text{HClO}_3$  is chloric acid, and  $\text{HClO}_4$  is perchloric acid.

### Th-6 Anions derived from oxyacids (oxyanions)

## Basic Inorganic Nomenclature

- (i) Anion derived from an oxyacid by removal of one or more  $\text{H}^+$  ions is termed as oxyanion.

**Rule :** If the oxyacid is – ic acid, suffix - ate is used with oxy-anion.

For example

$\text{CO}_3^{2-}$	carbonate (from $\text{H}_2\text{CO}_3$ )
$\text{ZnO}_2^{2-}$	zincate
$\text{SiO}_3^{2-}$	silicate

- (ii) **Rule : If the oxyacid is - ous acid, suffix -ite is used with oxy-anion.**

**For example,**  $\text{NO}_2^-$  (nitrite) is derived from  $\text{HNO}_2$  (nitrous acid), and  $\text{SO}_3^{2-}$  (sulphite) is derived from  $\text{H}_2\text{SO}_3$  (sulphurous acid)

- (iii) **Rule : If the oxyacid has prefixes per-or hypo-, the oxyanion will have same prefixes.**

**For example,**  $\text{ClO}_4^-$  perchlorate ion from  $\text{HClO}_4$ , perchloric acid,  $\text{ClO}^-$  hypochlorite ion from  $\text{HClO}$ , hypochlorous acid

Remember these names !

$\text{SO}_4^{2-}$	Sulphate
$\text{SO}_3^{2-}$	Sulphite
$\text{NO}_3^-$	Nitrate
$\text{NO}_2^-$	Nitrite
$\text{SnO}_3^{2-}$	Stannate
$\text{SnO}_2^{2-}$	Stannite
$\text{PbO}_3^{2-}$	Plumbate
$\text{PbO}_2^{2-}$	Plumbite

- (iv) **Anions containing replacable hydrogen ions**

**Polyprotic acid.** Any acid containing more than one replacable hydrogens is said to be a polyprotic acid.

- (v) **Replacable hydrogens.** H atoms which can be lost as  $\text{H}^+$  in reactions with a base. H atoms connected to O atoms in oxyacids are all replacable. If all the replacable hydrogens are removed, we obtain the anions discussed in the sections above. However, in all the polyprotic acids it is always possible to remove less than the maximum number of replacable hydrogens. e.g.  $\text{H}_3\text{PO}_4$  is triprotic. We can remove one, two or three  $\text{H}^+$  ions from it to generate  $\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$  and  $\text{PO}_4^{3-}$ .

You are already familiar with phosphate ion,  $\text{PO}_4^{3-}$ . The other two anions,  $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$  still contain H atoms that are replacable. We consider their nomenclature in this section.

- (vi) **Rule-1 :** A prefix bi- (old notation) or hydrogen – (IUPAC notation) is attached to the name of anion.

- (vii) **Rule-2 :** For triprotic or higher acids, numerical prefixes (e.g. mono, bi, tri) are also used to indicate the number of replacable H atoms left in the sample).

eg.  $\text{HCO}_3^-$  is bicarbonate or hydrogen carbonate

$\text{HSO}_3^-$  bisulphite or hydrogen sulphite

$\text{HS}^-$  bisulphide or hydrogen sulphide etc.

when anion has –3 charge,

e.g.  $\text{PO}_4^{3-}$  then following possibilities arise.

$\text{HPO}_4^{2-}$  monohydrogen phosphate,

$\text{H}_2\text{PO}_4^-$  dihydrogen phosphate.

### Th-7 Miscellaneous Anions (To be comitted to memory)

Anion	Name
$\text{HO}^-$	Hydroxide ion
$\text{O}_2^{2-}$	Peroxide ion
$\text{O}_2^-$	Superoxide ion
$\text{S}_2^{2-}$	Disulphide ion
$\text{I}_3^-$	Triiodide ion
$\text{N}_3^-$	Azide ion
$\text{NH}^-$	Imide ion
$\text{NH}_2^-$	Amide ion
$\text{CN}^-$	Cyanide ion
$\text{C}_2^{2-}$	Acetylide ion
$\text{O}_3^-$	Ozonide ion
$\text{MnO}_4^{2-}$	Manganate ion
$\text{MnO}_4^-$	Permanganate ion
$\text{SCN}^-$	Thiocyanate ion
$\text{S}_2\text{O}_3^{2-}$	Thiosulphate ion
$\text{CH}_3\text{COO}^-$	Acetate ion
$\text{C}_2\text{O}_4^{2-}$	Oxalate ion

### Th-8 Method of writing formula of an ionic compound

In order to write the formula of an ionic compound which is made up of two ions (simple or polyatomic) having net charges  $x$  and  $y$  respectively, follow the following procedure.

- Write the symbols of the ions side by side in such a way that positive ion is at the left and negative ion at the right as AB.
- Write their charges on the top of each symbol as  $A^x B^y$ .

- Now apply criss-cross rule as

i.e. formula  $A_y B_x$ .

- Cancel out any common factor (or HCF).

#### Examples :

1.	Calcium chloride	$\begin{matrix} 2 & 1 \\ \swarrow & \searrow \\ \text{Ca} & \text{Cl} \end{matrix} = \text{CaCl}_2$
2.	Aluminium oxide	$\begin{matrix} 3 & 2 \\ \swarrow & \searrow \\ \text{Al} & \text{O} \end{matrix} = \text{Al}_2\text{O}_3$
3.	Potassium phosphate	$\begin{matrix} 1 & 3 \\ \swarrow & \searrow \\ \text{K} & \text{PO}_4 \end{matrix} = \text{K}_3\text{PO}_4$
4.	Magnesium nitride	$\begin{matrix} 2 & 3 \\ \swarrow & \searrow \\ \text{Mg} & \text{N} \end{matrix} = \text{Mg}_3\text{N}_2$
5.	Calcium oxide	$\begin{matrix} 2 & 2 \\ \swarrow & \searrow \\ \text{Ca} & \text{O} \end{matrix} = \text{Ca}_2\text{O}_2$
6.	Ammonium sulphate	$\begin{matrix} 1 & 2 \\ \swarrow & \searrow \\ \text{NH}_4 & \text{SO}_4 \end{matrix} = (\text{NH}_4)_2\text{SO}_4$

Cancelling the common factor, answer is  $\text{CaO}$

### Th.9 : Some important points :

- If both element are non-metallic then more electronegative element is anionic part  
 $\text{As}_2\text{O}_3$  – arsenic (III) oxide  
 $\text{OF}_2$  – oxygen di fluoride,  
 $\text{ICl}_3$  – Iodine trichloride
- pyro name is attached with acid if it is derived by removing one water molecule from two acid molecules.

Two acid molecules  $\xrightarrow{-\text{H}_2\text{O}}$  pyro acid,  
 $\text{N, C, Cl, Br}$ , not forms pyroxy acids  
 $2\text{HClO}_4 \xrightarrow{-\text{H}_2\text{O}} \text{Cl}_2\text{O}_7$  not oxoacid it is an oxide

- Meta acid:** If one water molecule is removing from one acid molecule then meta acid is obtained.

One acid molecule  $\xrightarrow{-\text{H}_2\text{O}}$  meta acid,

$\text{N, C, S, Cl}$ , not forms metaoxy  
 only  $\text{Si, P, B}$  forms metaoxy acids,

- Naming of oxoanions derived from oxyacids**

– **ic** acid  $\equiv$  – ate

– **us** acid  $\equiv$  – ite

- There are some more anions which are very common like :

$\text{CrO}_4^{2-}$  – Chromate (name is derived from  $\text{SO}_4^{2-}$  sulphate as all features are same)

$\text{FeO}_4^{2-}$  – ferrate

$\text{MoO}_4^{2-}$  – molybdate

$\text{WO}_4^{2-}$  – tungstate

$\text{MnO}_4^{2-}$  – manganate

corresponding acids can be

$\text{H}_2\text{CrO}_4$  – chromic acid

$\text{H}_2\text{MnO}_4$  – manganic acid

$\Rightarrow$  Higher oxidation state of manganese  $\equiv$

$^{+7}\text{MnO}_4^-$

So called permanganate,  $\text{HMnO}_4$   
 permanganic acid

- Polysulphides**

$\text{S}_x^{2-}$  ( $x = 2, 3, 4, 5, \dots$ )

structures  $\text{S}_2^{2-}$   $^-\text{S} - \text{S}^-$  disulphide

$\text{S}_3^{2-}$   $\begin{matrix} & \text{S} & \\ ^-\text{S} & & \text{S}^- \end{matrix}$  trisulphide

$\text{S}_4^{2-}$   $\begin{matrix} & ^-\text{S} & & \text{S}^- \\ & \diagdown & \diagup & \\ & \text{S} & & \text{S} \end{matrix}$  tetra sulphide

Sodium disulphide  $\equiv \text{Na}_2\text{S}_2$

- Sulphate & thiosulphate (hypo)**

When ever oxygen of normal compound is replaced with sulphur then thio word is used before name of normal compound

## Basic Inorganic Nomenclature

alcohol –OH      Thioalcohol –SH  
 ether –O–      Thioether –S–  
 sulphate  $\text{SO}_4^{2-}$       Thiosulphate ( $\text{S}_2\text{O}_3^{2-}$ )

\*

Cyanate ion & Thiocyanate ion  
 Cyanic acid (HOCN)

(viii) **Metal cations** – Higher oxidation state of  
 Cations ends with ic & lower by – us

$\text{Fe}^{3+}$  – ferric       $\text{Cu}^{2+}$  – cupric  
 $\text{Fe}^{2+}$  – ferrous       $\text{Cu}_2^{2+}$  – cuprous  
 $\text{Hg}^{2+}$  – mercuric  
 $\text{Hg}_2^{2+}$  – mercurous

(ix) **Xenon :**

$\text{H}_4\text{XeO}_6$  – perxenic acid  
 $\text{XeO}_6^{4-}$  – perxenate ion

$\text{H}_2\text{XeO}_4$  – Xenic acid  
 $\text{XeO}_4^{2-}$  – Xenate ion

**Table-2: Difference between Atoms and ions**

	Atoms		Ions
1	Atoms are perfectly neutral	1	Ions are charged particles containing one or more atoms.
2	In atoms, the number of protons is equal to the number of electrons. Na (protons 11, electrons 11); Cl (protons 17, electrons 17).	2	In cations (positively charged ions), number of protons is more than the number of electrons. In anions (negatively charged ions) the no. of protons is less than the number of electrons. e.g. $\text{Na}^+$ (protons 11, electrons 10). $\text{Cl}^-$ (protons 17, electrons 18)
3	Except noble gases, atoms have less than 8 electrons in the outermost orbit e.g. Na : 2, 8, 1; Ca : 2, 8, 8, 2; Cl : 2, 8, 7; S : 2, 8, 6.	3	Ions have generally 8 electrons in the outermost orbit, i.e., $ns^2np^6$ configuration. $\text{Na}^+$ : 2, 8; $\text{Cl}^-$ : 2, 8, 8; $\text{Ca}^{2+}$ : 2, 8, 8
4	Chemical activity is due to loss or gain or sharing of electrons as to acquire noble gas configuration.	4	The chemical activity is due to the charge on the ion. Oppositely charged ions are held together by electrostatic forces.

Table - 3 : Naming of Oxyacid

Table - 3 : Naming of Oxyacid							
Acid end with IC suffix		Suffix-ous		Prefix -per ; suffix-ic			Prefix -pyro
Formula	Name	Formula	Name	Formula	Name	Formula	Name
H <sub>3</sub> BO <sub>3</sub>	Orthoboric acid	HNO <sub>2</sub>	Nitrous Acid	HNO <sub>4</sub>	Peroxyntiric acid	H <sub>4</sub> P <sub>2</sub> O <sub>7</sub>	Pyrophosphoric acid
H <sub>2</sub> CO <sub>3</sub>	Carbonic acid	H <sub>2</sub> SO <sub>3</sub>	Sulphurous acid	H <sub>3</sub> PO <sub>5</sub>	Peroxy monophosphoric acid	H <sub>4</sub> P <sub>2</sub> O <sub>5</sub>	Pyrophosphrous acid
HONC	Isocyanic acid	H <sub>2</sub> S <sub>2</sub> O <sub>5</sub>	Disulphurous acid	H <sub>4</sub> P <sub>2</sub> O <sub>5</sub>	Peroxy diphosphric acid	H <sub>4</sub> B <sub>2</sub> O <sub>5</sub>	Pyroboric acid
HO-CN	Cyanic acid	HClO <sub>2</sub>	Chlorous acid	H <sub>2</sub> SO <sub>5</sub>	Peroxy mono sulphuric acid	H <sub>6</sub> Si <sub>2</sub> O <sub>7</sub>	Pyro siliclic acid
HNO <sub>3</sub>	Nitric Acid	Prefix - Hypo ; suffix-ic		H <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	Peroxy disulphuric acid	H <sub>2</sub> S <sub>2</sub> O <sub>7</sub>	Pyrosulphuric acid
H <sub>2</sub> NO <sub>2</sub>	Nitroxylic acid	H <sub>2</sub> N <sub>2</sub> O <sub>2</sub>	Hyponitrous acid	HClO <sub>4</sub>	Perchloric acid		
H <sub>3</sub> PO <sub>4</sub>	Orthophosphoric acid	HClO	Hypochlorous acid	Prefix-thio			
H <sub>2</sub> SO <sub>4</sub>	Sulphuric acid	Prefix-meta ; suffix-ic		H <sub>2</sub> S <sub>2</sub> O <sub>3</sub>	Thio sulphuric acid		
HClO <sub>3</sub>	Chloric acid	(HBO <sub>2</sub> ) <sub>n</sub>	Metaboric acid	H <sub>2</sub> S <sub>2</sub> O <sub>2</sub>	Thio sulphurous acid		
H <sub>2</sub> S <sub>2</sub> O <sub>6</sub>	Dithionic acid	(HPO <sub>3</sub> ) <sub>n</sub>	Meta phosphoric acid	H <sub>2</sub> S <sub>2</sub> O <sub>6</sub>	Dithionic acid		
				H <sub>2</sub> S <sub>2</sub> O <sub>4</sub>	Dithionous acid
